

Bloginfo Shortcode

Last updated on: MAY 14, 2010

The `bloginfo()` function in WordPress gives you access to lots of useful information about your site. See [the complete list](#). To access all these values from inside Page/Post content itself, we can make a shortcode to return the values. Add this to your `functions.php` file in your theme:

PHP

```
function digwp_bloginfo_shortcode( $atts ) {
    extract(shortcode_atts(array(
        'key' => '',
    ), $atts));
    return get_bloginfo($key);
}
add_shortcode('bloginfo', 'digwp_bloginfo_shortcode');
```

Now you can output any of the values by calling that shortcode with "key". For example, the name of your site:

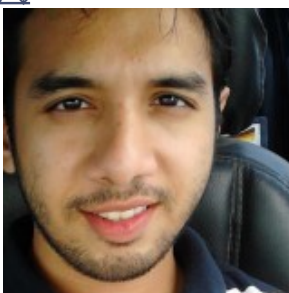

HTML

```
[bloginfo key='name']
```

Or directly to images in your theme folder:

HTML

```
/images/logo.jpg" alt="<?php do_shortcode('[bloginfo key='name']'); ?> logo" />
```

You would need the `do_shortcode()` if you are using it in the .php files that is true. However, why would you want to use the shorcode in php files if you already can do the `bloginfo('url');`. The shortcode is for posts/pages use.

THANK. YOU. I spent the last two and a half hours trying to figure out how to get relative image paths working from within a WordPress page, and was about to settle for using the WordPress image uploader. Now I can still work in code, thank God. Credited within my functions.php page.
